Rare Event Rule for Inferential Statistics:

If, under a given assumption, the probability of a particular observed event is extremely small, we conclude that the assumption is probably not correct.

Statisticians use the rare event rule for inferential statistics.

Section 4-2 Basic Concepts of Probability

Key Concept

This section presents three approaches to finding the probability of an event.

The most important objective of this section is to learn how to interpret probability values.

Part 1

Basics of Probability

Events and Sample Space

Event

any collection of results or outcomes of a procedure

Simple Event

an outcome or an event that cannot be further broken down into simpler components

Sample Space

for a procedure consists of all possible simple events; that is, the sample space consists of all outcomes that cannot be broken down any further

Notation for Probabilities

P - denotes a probability.

A, B, and C - denote specific events.

P(A) - denotes the probability of event A occurring.

Basic Rules for Computing Probability

Rule 1: Relative Frequency Approximation of Probability

Conduct (or observe) a procedure, and count the number of times event A actually occurs. Based on these actual results, P(A) is approximated as follows:

$$P(A) = \frac{\text{# of times } A \text{ occurred}}{\text{# of times procedure was repeated}}$$

Basic Rules for Computing Probability - continued

Rule 2: Classical Approach to Probability (Requires Equally Likely Outcomes)

Assume that a given procedure has *n* different simple events and that each of those simple events has an equal chance of occurring. If event *A* can occur in *s* of these *n* ways, then

$$P(A) = \frac{S}{n} = \frac{\text{number of ways } A \text{ can occur}}{\text{number of different simple events}}$$

Basic Rules for Computing Probability - continued

Rule 3: Subjective Probabilities

P(*A*), the probability of event *A*, is estimated by using knowledge of the relevant circumstances.

Law of Large Numbers

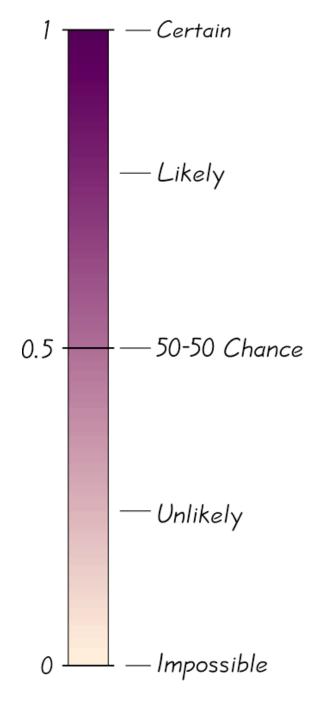

As a procedure is repeated again and again, the relative frequency probability of an event tends to approach the actual probability.

Probability Limits

Always express a probability as a fraction or decimal number between 0 and 1.

- The probability of an impossible event is 0.
- The probability of an event that is certain to occur is 1.
- For any event A, the probability of A is between 0 and 1 inclusive. That is, $0 \le P(A) \le 1$.

Possible Values for Probabilities

Complementary Events

The complement of event A, denoted by \overline{A} , consists of all outcomes in which the event A does not occur.

Rounding Off Probabilities

When expressing the value of a probability, either give the exact fraction or decimal or round off final decimal results to three significant digits. (Suggestion: When a probability is not a simple fraction such as 2/3 or 5/9, express it as a decimal so that the number can be better understood.)

Part 2

Beyond the Basics of Probability: Odds

Odds

The actual odds against event A occurring are the ratio P(A)/P(A), usually expressed in the form of a:b (or "a to b"), where a and b are integers having no common factors.

The actual odds in favor of event A occurring are the ratio P(A)/P(A), which is the reciprocal of the actual odds against the event. If the odds against A are a:b, then the odds in favor of A are b:a.

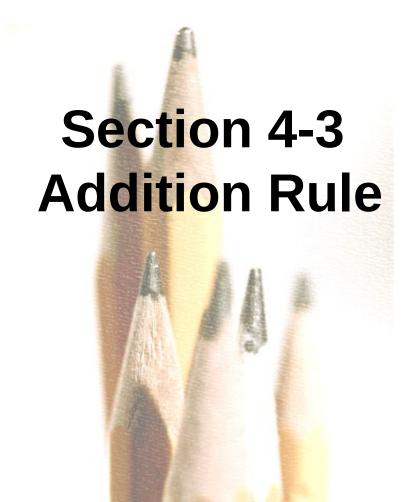

The payoff odds against event A occurring are the ratio of the net profit (if you win) to the amount bet.

payoff odds against event A = (net profit) : (amount bet)

Recap

In this section we have discussed:

- * Rare event rule for inferential statistics.
- Probability rules.
- Law of large numbers.
- Complementary events.
- * Rounding off probabilities.
- Odds.

Key Concept

This section presents the addition rule as a device for finding probabilities that can be expressed as P(A or B), the probability that either event A occurs or event B occurs (or they both occur) as the single outcome of the procedure.

The key word in this section is "or." It is the *inclusive or*, which means either one or the other or both.

Compound Event

Compound Event

any event combining 2 or more simple events

Notation

P(A or B) = P (in a single trial, event A occursor event B occurs or they both occur)

General Rule for a Compound Event

When finding the probability that event *A* occurs or event *B* occurs, find the total number of ways *A* can occur and the number of ways *B* can occur, but find that total in such a way that no outcome is counted more than once.

Compound Event

Formal Addition Rule

$$P(A \text{ or } B) = P(A) + P(B) - P(A \text{ and } B)$$

where *P*(*A* and *B*) denotes the probability that *A* and *B* both occur at the same time as an outcome in a trial of a procedure.

Compound Event

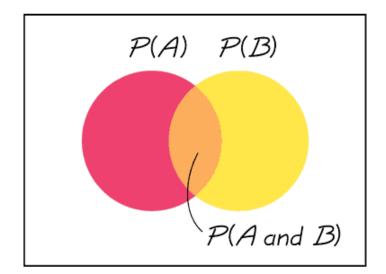

Intuitive Addition Rule

To find P(A or B), find the sum of the number of ways event A can occur and the number of ways event B can occur, adding in such a way that every outcome is counted only once. P(A or B) is equal to that sum, divided by the total number of outcomes in the sample space.

Disjoint or Mutually Exclusive

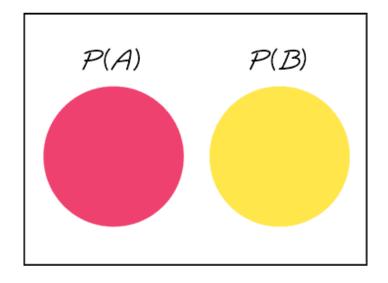

Events A and B are disjoint (or mutually exclusive) if they cannot occur at the same time. (That is, disjoint events do not overlap.)

Total Area = 1

Venn Diagram for Events That Are Not Disjoint

Total Area = 1

Venn Diagram for Disjoint Events

Complementary Events

P(A) and $P(\overline{A})$ are disjoint

It is impossible for an event and its complement to occur at the same time.

Rule of Complementary Events

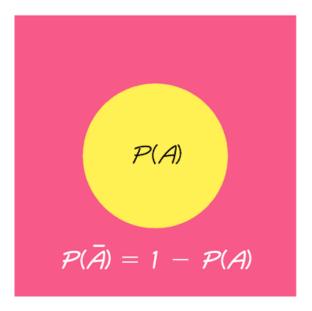

$$P(A) + P(\overline{A}) = 1$$

$$P(\overline{A}) = 1 - P(A)$$

$$P(A) = 1 - P(\overline{A})$$

Venn Diagram for the Complement of Event A

Recap

In this section we have discussed:

- Compound events.
- Formal addition rule.
- Intuitive addition rule.
- Disjoint events.
- Complementary events.

Section 4-4 Multiplication Rule: Basics

Key Concept

The basic multiplication rule is used for finding P(A and B), the probability that event A occurs in a first trial and event B occurs in a second trial.

If the outcome of the first event *A* somehow affects the probability of the second event *B*, it is important to adjust the probability of *B* to reflect the occurrence of event *A*.

Notation

P(A and B) =
P(event A occurs in a first trial and
event B occurs in a second trial)

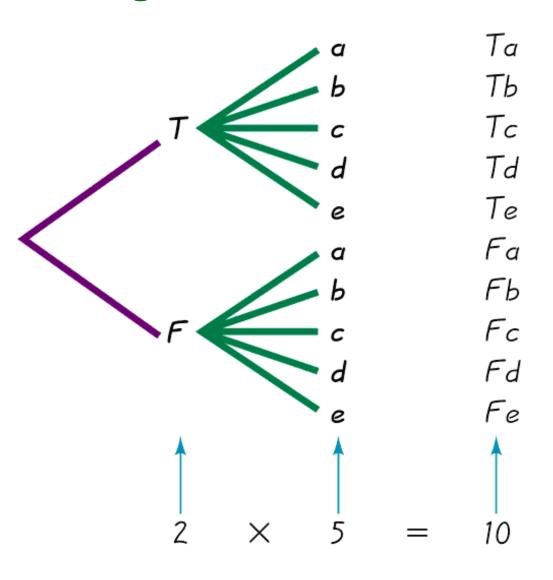

Tree Diagrams

A tree diagram is a picture of the possible outcomes of a procedure, shown as line segments emanating from one starting point. These diagrams are sometimes helpful in determining the number of possible outcomes in a sample space, if the number of possibilities is not too large.

Tree Diagrams

This figure summarizes the possible outcomes for a true/false question followed by a multiple choice question.

Note that there are 10 possible combinations.

Conditional Probability Key Point

We must adjust the probability of the second event to reflect the outcome of the first event.

Conditional Probability Important Principle

The probability for the second event *B* should take into account the fact that the first event *A* has already occurred.

Notation for Conditional Probability

P(B|A) represents the probability of event B occurring after it is assumed that event A has already occurred (read B|A as "B given A.")

Dependent and Independent

Two events A and B are independent if the occurrence of one does not affect the probability of the occurrence of the other. (Several events are similarly independent if the occurrence of any does not affect the probabilities of the occurrence of the others.) If A and B are not independent, they are said to be dependent.

Dependent Events

Two events are dependent if the occurrence of one of them affects the *probability* of the occurrence of the other, but this does not necessarily mean that one of the events is a *cause* of the other.

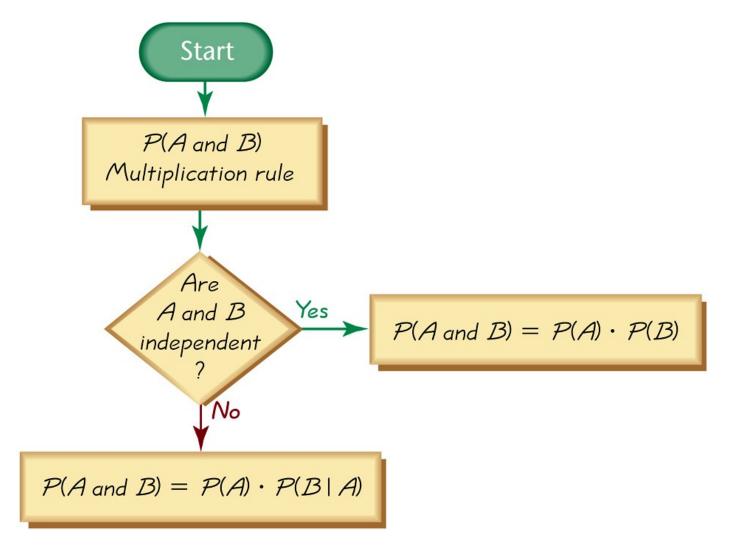

Formal Multiplication Rule

- $P(A \text{ and } B) = P(A) \cdot P(B|A)$
- Note that if A and B are independent events, P(B|A) is really the same as P(B).

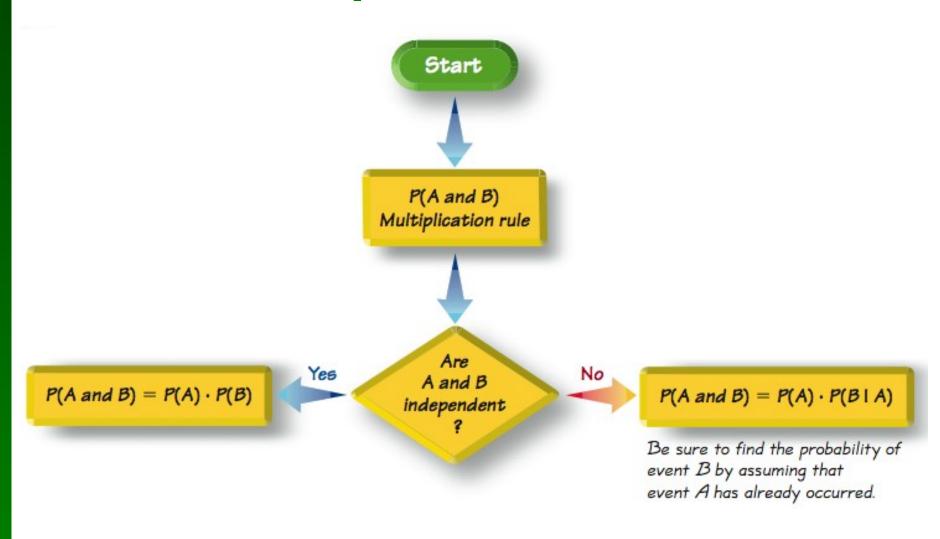

Intuitive Multiplication Rule

When finding the probability that event *A* occurs in one trial and event *B* occurs in the next trial, multiply the probability of event *A* by the probability of event *B*, but be sure that the probability of event *B* takes into account the previous occurrence of event *A*.

Applying the Multiplication Rule

Applying the Multiplication Rule

Caution

When applying the multiplication rule, always consider whether the events are independent or dependent, and adjust the calculations accordingly.

Multiplication Rule for Several Events

In general, the probability of any sequence of independent events is simply the product of their corresponding probabilities.

Treating Dependent Events as Independent

Some calculations are cumbersome, but they can be made manageable by using the common practice of treating events as independent when small samples are drawn from large populations. In such cases, it is rare to select the same item twice.

The 5% Guideline for Cumbersome Calculations

If a sample size is no more than 5% of the size of the population, treat the selections as being independent (even if the selections are made without replacement, so they are technically dependent).

Principle of Redundancy

One design feature contributing to reliability is the use of redundancy, whereby critical components are duplicated so that if one fails, the other will work. For example, single-engine aircraft now have two independent electrical systems so that if one electrical system fails, the other can continue to work so that the engine does not fail.

Summary of Fundamentals

- In the addition rule, the word "or" in P(A or B) suggests addition. Add P(A) and P(B), being careful to add in such a way that every outcome is counted only once.
- ❖ In the multiplication rule, the word "and" in P(A and B) suggests multiplication. Multiply P(A) and P(B), but be sure that the probability of event B takes into account the previous occurrence of event A.

Recap

In this section we have discussed:

- ightharpoonup Notation for P(A and B).
- Tree diagrams.
- Notation for conditional probability.
- Independent events.
- Formal and intuitive multiplication rules.

Section 4-5 Multiplication Rule: Complements and Conditional Probability

Key Concepts

Probability of "at least one": Find the probability that among several trials, we get at least one of some specified event.

Conditional probability: Find the probability of an event when we have additional information that some other event has already occurred.

Complements: The Probability of "At Least One"

"At least one" is equivalent to "one or more."

The complement of getting at least one item of a particular type is that you get no items of that type.

Finding the Probability of "At Least One"

To find the probability of at least one of something, calculate the probability of none, then subtract that result from 1. That is,

P(at least one) = 1 - P(none).

Conditional Probability

A conditional probability of an event is a probability obtained with the additional information that some other event has already occurred. P(B|A) denotes the conditional probability of event B occurring, given that event A has already occurred, and it can be found by dividing the probability of events A and B both occurring by the probability of event A:

$$P(B|A) = \frac{P(A \text{ and } B)}{P(A)}$$

Intuitive Approach to Conditional Probability

The conditional probability of *B* given *A* can be found by assuming that event *A* has occurred, and then calculating the probability that event *B* will occur.

Confusion of the Inverse

To incorrectly believe that P(A|B) and P(B|A) are the same, or to incorrectly use one value for the other, is often called confusion of the inverse.

Recap

In this section we have discussed:

- Concept of "at least one."
- Conditional probability.
- Intuitive approach to conditional probability.

Section 4-6 Probabilities Through Simulations

Key Concept

In this section we use simulations as an alternative approach to finding probabilities. The advantage to using simulations is that we can overcome much of the difficulty encountered when using the formal rules discussed in the preceding sections.

Simulation

A simulation of a procedure is a process that behaves the same way as the procedure, so that similar results are produced.

Simulation Example

Gender Selection In a test of the MicroSort method of gender selection developed by the Genetics & IVF Institute, 127 boys were born among 152 babies born to parents who used the YSORT method for trying to have a baby boy. In order to properly evaluate these results, we need to know the probability of getting at least 127 boys among 152 births. assuming that boys and girls are equally likely. Assuming that male and female births are equally likely, describe a simulation that results in the genders of 152 newborn babies.

Solution

One approach is simply to flip a fair coin 152 times, with heads representing females and tails representing males. Another approach is to use a calculator or computer to randomly generate 152 numbers that are 0s and 1s, with 0 representing a male and 1 representing a female. The numbers must be generated in such a way that they are equally likely. Here are typical results:

Simulation Examples

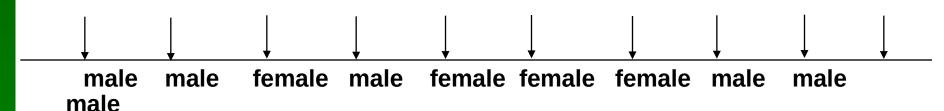

Solution 1:

Flipping a fair coin 100 times where heads = female tails = male Н Н Н Н Н Н Н female female male female male male male female female female

Generating 0's and 1's with a computer or calculator where
 Solution 2: 0 = male

1 = **female**

0 0 1 0 1 1 1 0 0

Random Numbers

In many experiments, random numbers are used in the simulation of naturally occurring events. Below are some ways to generate random numbers.

- A table of random of digits
- STATDISK
- Minitab
- Excel
- TI-83/84 Plus calculator

Recap

In this section we have discussed:

The definition of a simulation.

* How to create a simulation.

Ways to generate random numbers.

Key Concept

In many probability problems, the big obstacle is finding the total number of outcomes, and this section presents several methods for finding such numbers without directly listing and counting the possibilities.

Fundamental Counting Rule

For a sequence of two events in which the first event can occur m ways and the second event can occur n ways, the events together can occur a total of $m \cdot n$ ways.

Notation

The factorial symbol! denotes the product of decreasing positive whole numbers.

For example,

$$4! = 4 \cdot 3 \cdot 2 \cdot 1 = 24.$$

By special definition, 0! = 1.

Factorial Rule

A collection of n different items can be arranged in order n! different ways. (This factorial rule reflects the fact that the first item may be selected in n different ways, the second item may be selected in n-1 ways, and so on.)

Permutations Rule (when items are all different)

Requirements:

- 1. There are *n* different items available. (This rule does not apply if some of the items are identical to others.)
- 2. We select r of the n items (without replacement).
- 3. We consider rearrangements of the same items to be different sequences. (The permutation of ABC is different from CBA and is counted separately.)

If the preceding requirements are satisfied, the number of permutations (or sequences) of r items selected from n available items (without replacement) is

$$n^P r = \frac{n!}{(n-r)!}$$

Permutations Rule (when some items are identical to others)

Requirements:

- 1. There are *n* items available, and some items are identical to others.
- 2. We select all of the *n* items (without replacement).
- 3. We consider rearrangements of distinct items to be different sequences.

If the preceding requirements are satisfied, and if there are n_1 alike, n_2 alike, . . . n_k alike, the number of permutations (or sequences) of all items selected without replacement is

$$\frac{n!}{n_1! . n_2! n_k!}$$

Combinations Rule

Requirements:

- 1. There are *n* different items available.
- 2. We select r of the n items (without replacement).
- 3. We consider rearrangements of the same items to be the same. (The combination of ABC is the same as CBA.)

If the preceding requirements are satisfied, the number of combinations of r items selected from n different items is

$$_{n}C_{r}=\frac{n!}{(n-r)!\ r!}$$

Permutations versus Combinations

When different orderings of the same items are to be counted separately, we have a permutation problem, but when different orderings are not to be counted separately, we have a combination problem.

Recap

In this section we have discussed:

- The fundamental counting rule.
- The factorial rule.
- The permutations rule (when items are all different).
- The permutations rule (when some items are identical to others).
- The combinations rule.
